

Some notes on pentesting

Robert Malmgren, ROMAB

Senior security consultant

rom@romab.com

+46-708-330378

Why discuss pentests in a SCADA context: Reasons

- It has good entertainment or drama value: Seeing is believing
- CSO need budget boost?
- Political fight between CIO / IT operations and the people running the process IT system?
- Used to arm wrestle with the vendor?
- Security researchers / consultants on a PR trip?
- Technical hubris?
- Real reasons: e.g. changes in IT landscape, moving from island to full integrations with business IT systems.

Caveat emptor!

- **Obtaining security-by-testing** is a broken perception
 - test cases might be incomplete or wrong
 - tests might not reflect original or contemporary risk analysis
 - testers might not be skillful enough or having a bad day
 - test tools might not work as anticipated
 - Usage of another IP address, other user name or different software version might render very different results
 - etc
- But the alternatives are not realistic...
 - Security-obtained-because-software-based-on-standards
 - Pipe dreams, i.e. flawlessly designed software maintained by flawless operators
 - Certification will ensure all security bugs are non-existent.

Yeah, right...

The problems with pentests

- Many automated tools...
 - ...is unfit to use in **that** sensitive environment, e.g. to demanding
 - ...is not transparent, hence can you trust the software you plan to run
 - ...does not include support for **that** old vulnerabilities
 - ...certainly is not capable of testing **that** proprietary protocol
 - ...does not provide the answers to some of the fundamental questions, e.g. quality of risk assessment
- **The lack of positive results does not equal a secure system**

Technical assessments

- Can include pentest parts, but also includes
 - visual checks of physical & logical setup
 - manual checks of system/application/infrastructure setup & configuration
 - interviews sometime reveal more than technical tests, e.g. politics behind design decisions.
- The important part here is that audit/assessments are much more than pentests alone

Information sharing

"The good guys have CERT, and the bad guys have IRC.
Game over"

Marcus Ranum, anno 1995

Interpretation: We are **always lagging behind** in terms of knowledge of the latest vulnerabilities, or having the option to schedule an update window for the latest patches, etc

This, of course, is not only valid for pure information, but more importantly for source code, attack tools, etc.

Open vs unpublished research

- Since SCADA security is labeled Critical infrastructure & National security government labs vulnerability findings will not end up in an open source vulnerability scanner near you, hence you will not find all flaws even with the latest scanner version.
- SCADA/PCS vendors still have a long way to go to understand Internet age vulnerability handling, e.g. rapid response, being able to co-operate with flaw finders, having the right mindset for open or honest discussions with customers or third parties.

How to run the tests

- Black box & unannounced <-> White box & in cooperation with responsible staff on-site
- In a live environment some extra precautions must be taken:
 - Just target single-nodes in HA setups, ie netscans are dangerous
 - Using debug or test features of the setup
 - Some equipment might need to be disabled during the test session
 - Having people (vendor reps, operators, etc) on-call to be able to switch to manual routines or disaster recovery

Summary

- Doing pentests is really great, if....
 - ...done for the right reasons
 - ...the right precautions and safety measures are done
 - ...if you're ready to test your disaster recovery plan
 - ...having the right tests cases, right selection of tools and relevant checks
 - ...and using the methodology, still knowing that its built-in drawbacks

- The results from pen tests is more useful if combined into a more complete technical assessment

Still people rely on the obscurity factor
