

Unconventional Logging and Detection

Justin Henderson (@SecurityMapper)

About Me

Justin Henderson

- SEC555 Author / SEC455 and SEC530 Co-Author
- GSE #108 / Cyber Guardian Blue + Red / 60 certs
- Owner and Principal Consultant of H & A Security Solutions
- **Twitter:** @SecurityMapper
- **GitHub:** github.com/HASecuritySolutions
- And security hobbyist and community supporter
 - Collecting interns/contributors in bulk (research teams)
 - Release research to the community

Unconventional Tactics

Log Collection

- Focus on picking up logs
 - Without requiring agents on each endpoint
 - Or without agents entirely
- Upgrading logs
 - Adding context (log enrichment)

Methods work regardless of SIEM in use

Detection

Implement detection capabilities

- Without requiring security software or agents
- Remove requirement for remote polling software
 - osquery
 - SSH
 - WMI

Log Agents

Windows Event Forwarding

To collect logs using Windows event forwarding is a two-step process

- An event collector must be set up
- Then, either the collector must be configured to pull events or endpoints must be configured to push events

GPO is used to tell endpoints what logs to push

- Configuration of event selection is similar for push/pull

The end destination is intended to be Windows, not SIEM

Blind Drop

Windows event forwarding cannot ship file logs

- Only handles native Windows events

Business requirement may require no third-party agents

- Can be handled by using a blind file share

Requires a single file server to have a third-party agent or PowerShell script

- Share is created with write permissions only
- Log files are then saved to this share

Blind Drop with PowerShell Transcription Logging

List folder contents at root folder, write only on subfolders

The screenshot shows a Windows File Explorer window with the address bar set to `\\itfs01.corp.hasecuritysolutions.com\PSLogs`. The main pane displays a list of folders: 20181109, 20181110, 20181111, 20181112, 20181113, and 20181114. A red arrow points from the 20181113 folder in the main view to a detailed view of that folder. The detailed view shows a file named `PowerShell_transcript.IT-01.yowwczCa.20181130143536` with a date modified of 11/30/2018 2:35 PM.

Name	Date modified	Type
20181109	11/9/2018 11:58 PM	File folder
20181110		
20181111		
20181112		
20181113		
20181114		

Name	Date modified
PowerShell_transcript.IT-01.yowwczCa.20181130143536	11/30/2018 2:35 PM

Log Collection of Key Data Source != Good Data

A SIEM is often treated as a mainstream consumer of data

- Yet it should emphasize analysis and detection

Case Study / Example - Which would you rather analyze?

AppLocker Block Event

File =
PATH/SEC555_ROCKS.EXE
File Hash = empty
User = jhenderson
Policy Name = exe

%OSDRIVE%\SEC555_ROCKS.exe
was prevented from running.

Modified Block Event

File =
PATH/SEC555_ROCKS.EXE
File Hash = empty
User = jhenderson
Policy Name = exe
Signed = false
Signature = Unknown
Hashes = MD5|SHA1 hash here
Sandbox = 9/10 evilness rating

Getting Context

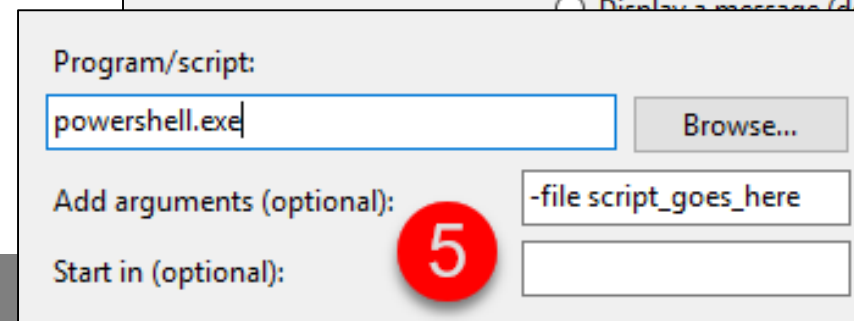

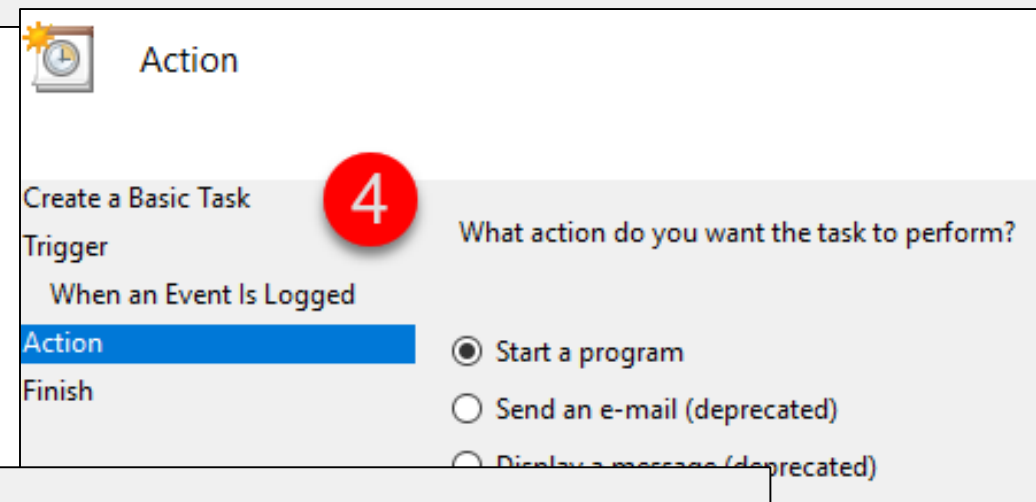

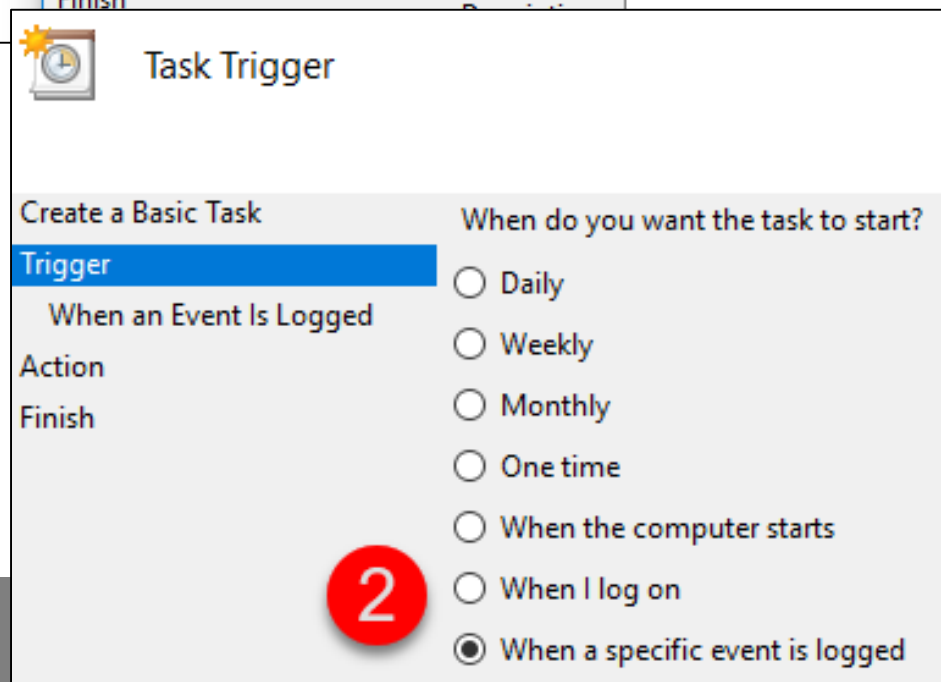

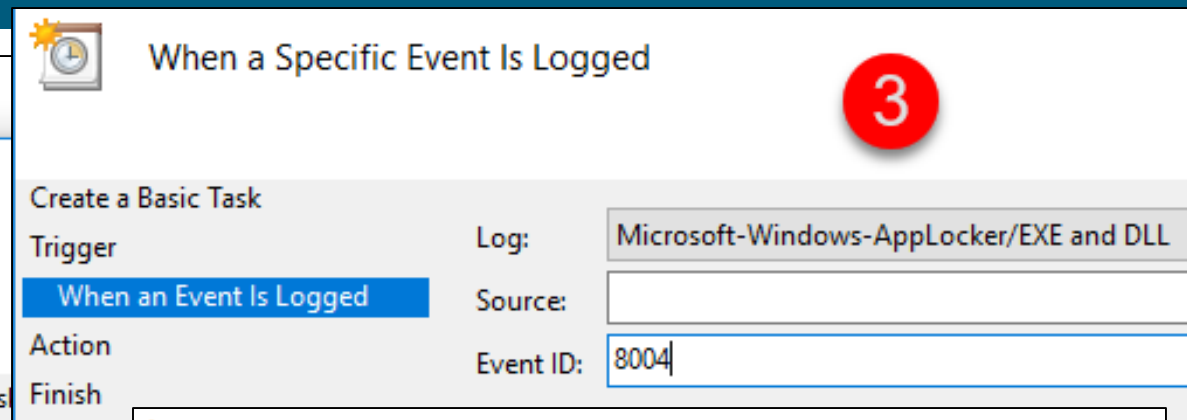

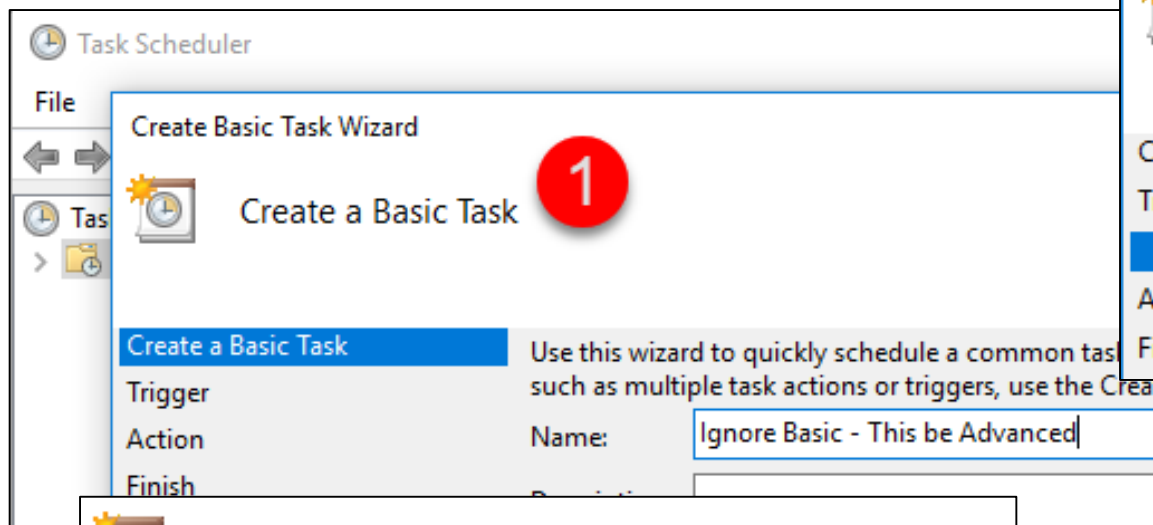

Problem is how to gain context with a SIEM (multiple options)

1. Log enrichment during **data ingestion** (Example - Logstash)
2. Log enrichment while **viewing the log** (Example - Splunk)
3. Log enrichment via **orchestration** (Example - Phantom)

Above implementations are tool specific (use of all would be ideal)

- And may be difficult to maintain / implement
- Any certain techniques do not scale well with above methods
 - Waiting for malware sandbox analysis takes minutes

Different Approach

Script Logic

When task schedule is triggered the script could do the following:

- Get the recent **8004** event ID from **AppLocker**
- Send the file to malware sandbox
- Run **sigcheck.exe** against file
- See if **Sysmon** events exist to find parent process info
- Perform any other additional checks
- Write a new custom log

Custom Logging with PowerShell

PowerShell makes writing custom logs easy

- Simply use Write-EventLog to generate a custom log
- If you want a custom channel, first, use New-EventLog

```
1 New-EventLog -LogName LogCampaign -Source CustomLogs
2 Write-EventLog -LogName LogCampaign -Source CustomLogs
  -EventId 31337 -EntryType Warning -Message "New and
  improved log goes here"
```

Can be used to generate logs that even basic log collectors can collect

- May remove the need for special log agents

PowerShell Generated Log

The screenshot shows the Windows Event Viewer application. The left-hand pane displays a tree view of event logs, with 'LogCampaign' under 'Applications and Services Logs' selected. A red arrow points to this selection. The main pane shows a list of two warning events for 'LogCampaign'. The top event is selected, and its details are shown in the 'General' tab. A red box highlights the event name 'Event 31337, CustomLogs', and a red arrow points to the text 'New and improved log goes here' in the description field. The 'Details' tab is also visible, showing metadata for the event.

Level	Date and Time
Warning	11/27/2018 10:17:19 AM
Warning	11/27/2018 10:17:12 AM

Event 31337, CustomLogs

General Details

New and improved log goes here

Log Name: LogCampaign
Source: CustomLogs
Event ID: 31337
Level: Warning
User: N/A
OpCode:
More Information: [Event Log Online Help](#)

Logged: 11/27/2018
Task Category: (1)
Keywords: Classic
Computer: LightforgeS

Offloading Job

Standard user privileges work with writing logs to Windows

- But custom channel must be created first
- Does not work to pre-built channels like **Security**
- Crafting log over network works as standard user

Possible to offload sensitive jobs off endpoints

- Example - Trigger custom log and copy file to blind share
 - Then perform automated analysis there
- Use SIEM to trigger automatic action

Custom Logging via Scripts

PowerShell

```
1 Install-Module Posh-Syslog
2 Import-Module Posh-Syslog
3 Send-SyslogMessage -Server "x.x.x.x"
  -Message 'Log message here' -Severity
  Informational -Facility syslog -Transport TCP
```

Python

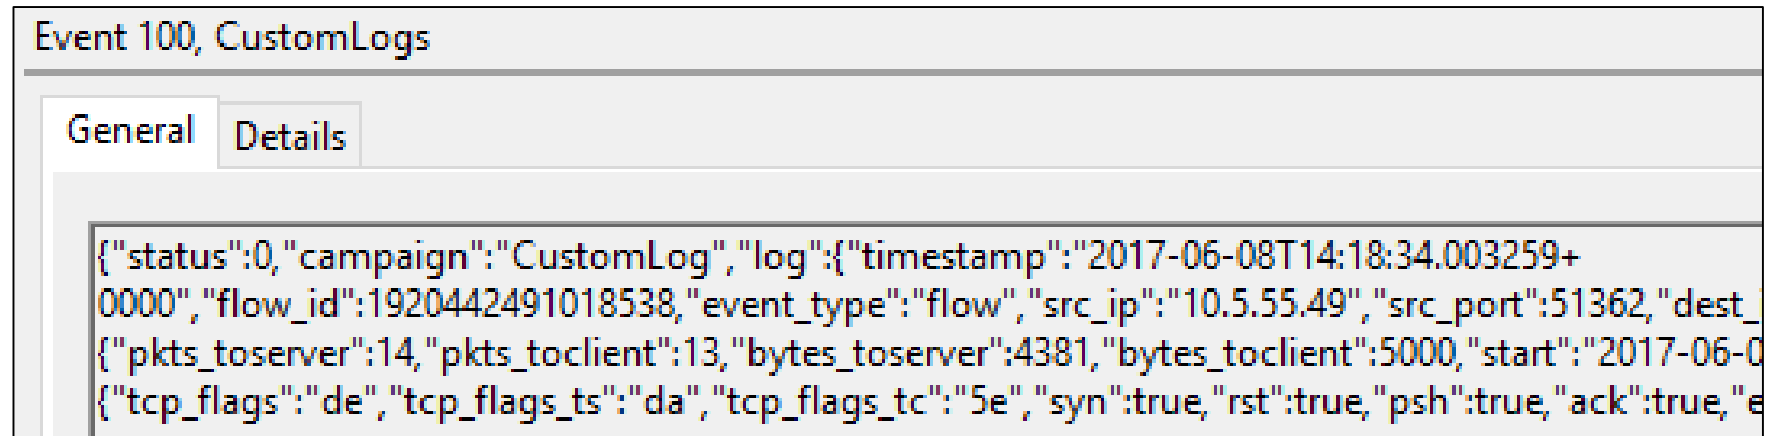

```
1 import logging
2 import logging.handlers
3 custom_logger = logging.getLogger('MyLogger')
4 custom_logger.setLevel(logging.INFO)
5 handler = logging.handlers.SysLogHandler
  (address = ('X.X.X.X', 514))
6 custom_logger.addHandler(handler)
7 custom_logger.info("Log message here")
```

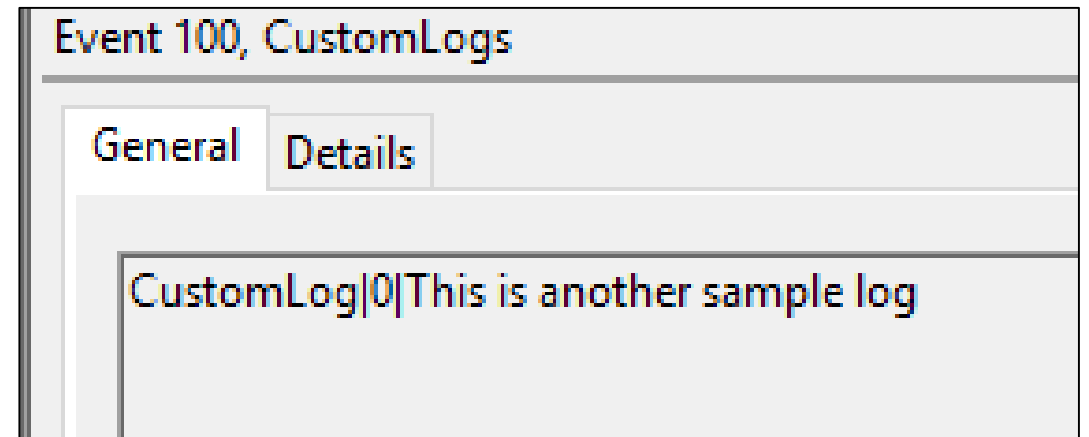

Custom Format

Scripting log allows output to be in any format

- CEF
- LEEF
- Syslog
- JSON
- Key-value
- CSV

The screenshot shows a log viewer interface with a title bar 'Event 100, CustomLogs'. Below the title bar are two tabs: 'General' and 'Details'. The 'Details' tab is selected, and the log entry is displayed in a text area. The log entry is a JSON object with the following structure: {"status":0,"campaign":"CustomLog","log":{"timestamp":"2017-06-08T14:18:34.003259+0000","flow_id":1920442491018538,"event_type":"flow","src_ip":"10.5.55.49","src_port":51362,"dest_ip":"10.5.55.49","pkts_toserver":14,"pkts_toclient":13,"bytes_toserver":4381,"bytes_toclient":5000,"start":"2017-06-08T14:18:34.003259+0000","end":"2017-06-08T14:18:34.003259+0000","tcp_flags":"de","tcp_flags_ts":"da","tcp_flags_tc":"5e","syn":true,"rst":true,"psh":true,"ack":true,"e...}}

The screenshot shows a log viewer interface with a title bar 'Event 100, CustomLogs'. Below the title bar are two tabs: 'General' and 'Details'. The 'Details' tab is selected, and the log entry is displayed in a text area. The log entry is a key-value pair: CustomLog|0|This is another sample log

Unconventional Logging

Collection

Multiple options outside of using agents to collect logs

- Script out / to Windows events
- Use script to send logs via syslog or custom formats
- Output as file to central file share
- Use Windows Event Forwarding

Enrichment

Take existing logs and make them better

- Windows Task Scheduler
 - To kick off script based on Windows Event ID
- Or read log with script

Then generate better log(s)

* Still need aggregator, search, and SOAR for other enrichment

Agentless Detection

Adversaries "live off the land" and use tools against you

- But defenders need to and should "live off the land"
- **PowerShell, Python, and Bash** provide scalable, easy to implement detection and response capabilities

Try running simple scripts on a re-occurring basis

- **Windows Task Scheduler** running every 5 minutes
- **Cron job** running every 1 minute
- Run at **startup script** that handles its own scheduling

Log Campaign - GitHub Project

```
PS C:\log_campaign> .\log_campaign.ps1 -Campaign ARPCache -Destination syslog -DestinationServer 10.5.55.2
PS C:\log_campaign> .\log_campaign.ps1 -Campaign ARPCache -Destination evtv -EventID 31337
```

Provides detection capabilities with logging
Campaigns

File Ingestion --->

Provides ability to read in files, convert them, and log to syslog or evtv

```
PS C:\log_campaign> .\log_campaign.ps1 -File .\test.txt
Text format found and selected. If you do not want this use -AutoFormat:$false
PS C:\log_campaign> .\log_campaign.ps1 -File .\test.csv
Delimited file found with , as the delimiter. If you do not want this use -AutoFormat:$false
PS C:\log_campaign> .\log_campaign.ps1 -File .\test.json
JSON format found and selected. If you do not want this use -AutoFormat:$false
```

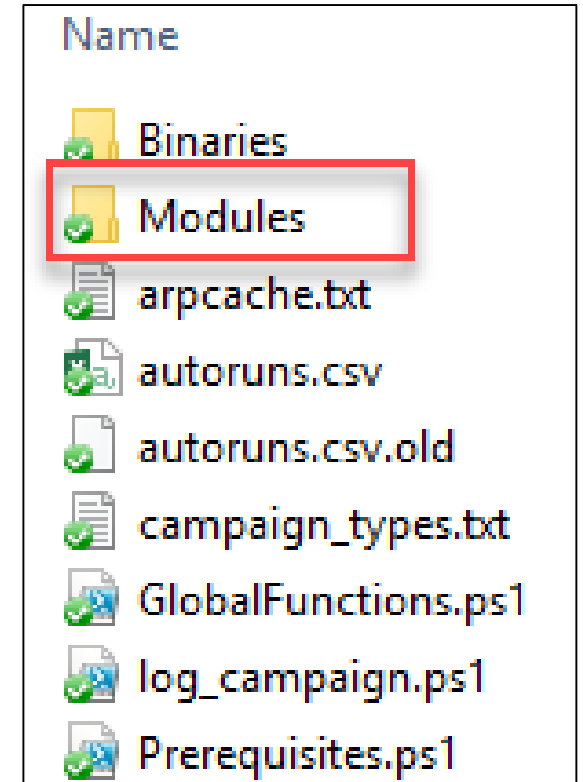

Modular Campaigns

Each Campaign is its own module

- Allows easy drop in of custom modules
- Or using pre-built modules

Example - **ARPCache.ps1** module

- On first run, saves ARP entry for default gateway
- Then generates log if MAC address changes
- Acts as an alert to ARP cache poisoning attacks

Autoruns.ps1 Module

Campaigns can call 3rd party binaries like **autorunsc.exe**

- Many organizations use autorunsc.exe for incident handling / forensics for finding persistence
- Works well for local or file server storage but not daily baseline to SIEM (or near real time monitoring)

Autoruns.ps1 module calls **autorunsc.exe**

- Generates logs only when new or changed entries found
- Can be run every X minutes without your SIEM dying

Baseline Data Sources

Good data requires getting your hands dirty

- May have to go "fetch" what you need

Useful data

- Active processes
- Certificates
- Drivers
- Host files
- Registry keys
- Route table
- Scheduled tasks
- Security status
- Services
- Shares
- Software
- USB devices
- Users and groups

Log Campaign - Scheduling

Log Campaign supports multiple methods of scheduling

- Control schedule via **Windows Task Scheduler**
- Implement schedule using **-Schedule** parameter
 - Supports per X minute repetitive scheduling
 - Great when combined with a startup task or script

```
.\log_campaign.ps1 -Campaign all -Schedule 1
```

Run all **Campaigns** or specific ones on custom schedules

Local Detection Strategies

- **Matching** (Blacklist) - Look for something that should not occur then generate alert
- **Anomaly** - Look for things that change
 - To save time and resources consider only sending "new" items
- **Change Monitoring** - Look for things that change
 - Treat as alert if change is not authorized / expected

Local use can be combined with things like **DeepBlueCLI**

- Any tool that can output to file may be easier to maintain

GitHub Link

Log Campaign can be found in this GitHub repo:

<https://github.com/HASecuritySolutions/LogCampaign>

Feel free to modify or make a Python or Bash equivalent
